

1. exercise

- write the function **get_num_count(num)**;
the function returns a dictionary with the count of all digits used in the number (do not use any libraries)

example:

`get_num_count("126181") -> {'0': 0, '1': 3, '2': 1, '3': 0, '4': 0, '5': 0, '6': 1, '7': 0, '8': 1, '9': 0}`

2. exercise

- write the function **get_min_med_max(sequence)**;
- the function receives a sequence of numbers or a string and returns a tuple with 3 values – the lowest, the median and the highest!

example:

`get_min_med_max([0,9,2,5,3]) → (0,3,9)`

`get_min_med_max([9,9,2,2,4,3]) → (2,3.5,9)`

`get_min_med_max("baaac") → ("a","a","c")`

`get_min_med_max("faaacb") → ("a","ab","f")`

3. exercise

- write the function **unique_words_count(sequence)** that takes a single string as input. This string may contain multiple words separated by spaces;
- extract all the unique words from the input string, ignoring case, and return the number of unique words as well as the words themselves.

example:

`unique_words_count("Python is fun and python is easy to learn") →`

7 unique words: "python", "is", "fun", "and", "easy", "to", "learn")
